

How to create a "Series" style collection

Upload a .zip file that contains your series. The .zip file should be 3.5GB or less. It should contain:

- a folder named "images"
- a folder named "animations" (if your series uses animations)
- a .json file named "metadata.json"

"images" folder

The images folder should contain images for each token, numbered sequentially starting at 1 (1.png, 2.png, 3.png, etc.). We currently support .png or .jpeg files for static images.

"animations" folder

If your project uses animations, include a folder named "animations" that includes video files for each token, numbered sequentially starting at 1 (1.mp4, 2.mp4, 3.mp4, etc.). We currently support .gif, .mp4 and .webp files for animations.

Note that to ensure consistent display, you'll need to include an "images" folder containing static versions with your project. This provides a fall-back static version for platforms that may not handle animations properly.

metadata.json file

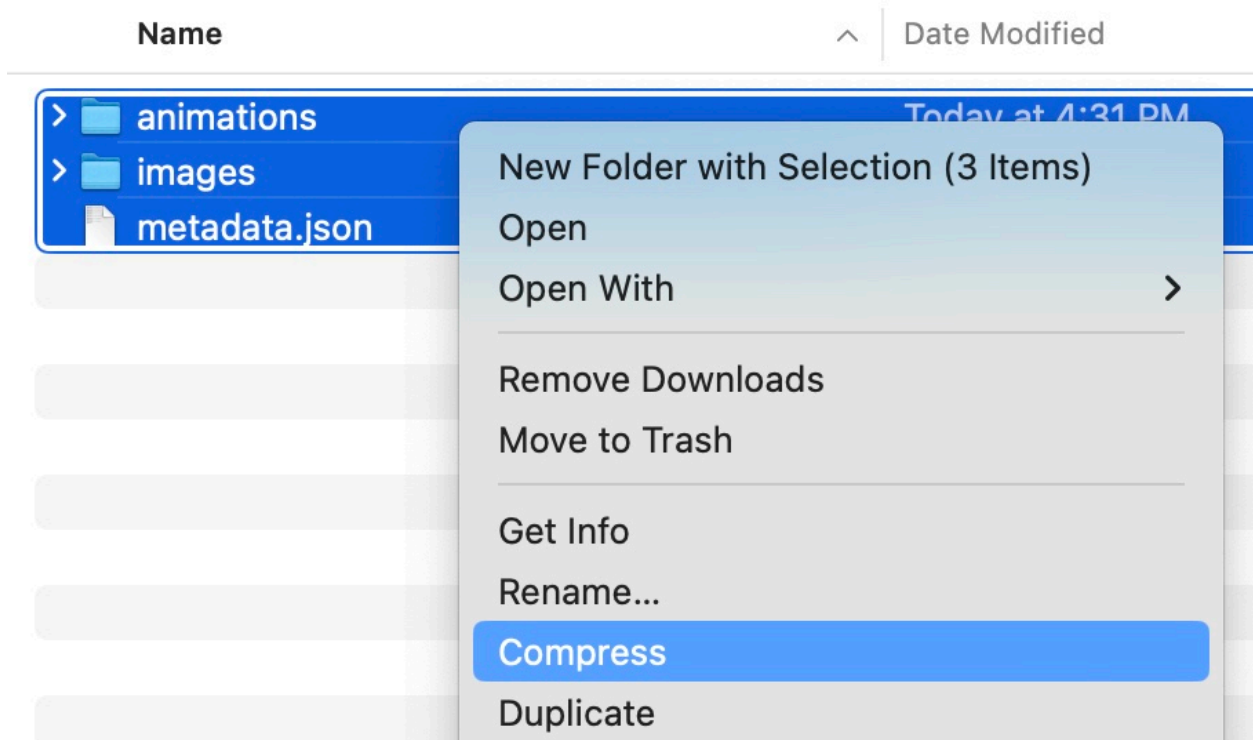

The metadata.json file provides the metadata traits for each token. By default, the items in the array are matched to the corresponding media file(s) in the images folder and (if relevant) animations folder. The first item in the array uses the first item in the images folder and/or the first file in the animations folder as its artwork.

You can specify the exact media file to use as the artwork for a specific token by adding `"imageRef": "file-name.png"` and/or `"animationRef": "file-name.mp4"` within the .json metadata. If desired, you can reuse the same media file for different tokens.

In your metadata.json file, use the keys `"name"` and `"description"` to specify the token's name and description respectively. If a `"name"` is not provided, tokens will be named `"#1"`, `"#2"`, `"#3"`, etc. You can add other keys to specify custom metadata traits.

Preparing your .zip file

Please make sure you zip the tokens folder and metadata.json file themselves, not a folder containing them.
